

Hospital Readmissions Overview

Objective: Reducing hospital readmissions by identifying high-risk groups and diagnoses, and improving post-discharge care plans to reduce operational costs and improve the quality of medical service.

Discharge Disposition Impact

Executive Summary & Key Insights

1. High Overall Readmission Rate

The hospital recorded an average readmission rate of 77.3%, exceeding the chronic-care benchmark range (65–75%).

This indicates potential gaps in post-discharge monitoring and patient follow-up care.

2. Medicare Patients Showed the Highest Readmission Rates

Medicare patients experienced the highest readmission rate at 95.4%.

This may reflect the vulnerability of elderly and chronic-condition patients.

3. Certain Diagnoses Were Associated with Elevated Risk

COPD, Sepsis, and Heart Failure showed the highest readmission percentages.

These conditions may require enhanced discharge planning and closer outpatient monitoring.

4. Longer Hospital Stays Correlated with Higher Complexity

Patients with severe comorbidities and diagnoses such as Sepsis and Stroke exhibited longer average lengths of stay.

This suggests increased treatment complexity and resource utilization.

5. Discharge Disposition Strongly Influenced Outcomes

Skilled Nursing and Home Health groups demonstrated notably high percentages across older age groups.

This highlights the importance of post-discharge care pathways in reducing readmissions.

6. Seasonal Variation Was Relatively Stable

Monthly readmission rates remained consistently high throughout the year, with slight increases toward December. ..
